Propagation...

Cont. from page 25
 hormone. Next wrap the cut with moist sphagnum moss. The ball of moss should be about six inches long and four inches wide. Use twine to hold the moss in place and cover the ball with plastic. Seal the edges and seam with tape.
 After several weeks, roots should be visible. When the roots have filled the

sphagnum moss, cut the layer from the stock plant just below the ball of moss and remove the plastic. Pot the layer immediately.
 The remaining portion of the stock plant can be used for cane cuttings to propagate more plants.
 Air layering is also a method of shortening plants that become leggy, such as dumbcane.

Runners

Runners are the creeping stems of plants with clusters of leaves at the joints or nodes. Some of the common house plants with runners are spider plant, Boston fern, apostle plant, mother-of-thousands, and pick-a-back plant.
 Roots form when the leaf clusters or stems come in contact with warm moist soil. After the roots have formed a new plant is made by separating the stem and leaf clusters from the original plant.

To propagate your home plants from runners, begin with a three inch flower pot filled with either sand, sphagnum moss, peat moss, vermiculite or soil. Place the leaf cluster on top of the soil and hold it in place with a hairpin. Keep the soil moist and in three to five weeks roots should form. The new plant is ready to be cut free from the runner.

Division is one of the easiest and quickest ways to produce new plants. Plants that produce stems at the base of the plant — such as snake plant, Begonia, cast-iron plant, African violet, English ivy, philodendron, and Periwinkle or vinca — can be divided.
 The best time to divide plants is during the dormant or rest period. Remove the plant from the container and separate the stock plant into smaller pieces, each piece having some roots. Pot them in a mixture of one part sand, two parts peat moss, and two parts loamy soil.
