

Biography Of A Bug

To keep ahead of garden insect pests, Michigan State University entomologists offer these tips on control:

BLACK VINE WEEVIL. Sometimes called the taxus weevil, this pest feeds at night upon broadleaf evergreens (such as the Japanese yew (taxus), rhododendron, azalea, mountain laurel and wisteria.

The black adult beetle feeds on the lower leaves of the plant. Leaf edges will appear to have half circles cut out of them. The Black Vine Weevil lays its eggs in July. Eggs hatch into grubs in August and burrow into the soil where they feed upon roots of shrubs until cold weather sets in.

The small white grubs overwinter and begin feeding on roots again in May. They pupate and mature as adults in June.

To control the Black Vine Weevil, it is suggested that two sprays of Sevin (follow directions by manufacturer) be used. Lower portions of the plant and the surrounding soil surface should be sprayed thoroughly before the adults lay their eggs.

MITES

The mite is nearly invisible to the naked eye, although it is one of the most destructive pests to shrubs, flowers and trees. Mites are not considered insects because they are more closely related to spiders.

Most species of the four-leg adults lay eggs. Under dry, hot conditions, mite populations increase rapidly. Heavy populations may cause leaves of deciduous trees to fall early or conifers to take on a brownish appearance.

Mites can be controlled by spraying foliage thoroughly with either Tordon or Kelthane. Applications should be repeated every four days for three weeks for maximum control. Kelthane kills adults and young, while Tordon kills eggs.

LEAFHOPPERS

These green to dark brown insects suck the juices from a large range of plants such as apples, raspberries, trees and some herbaceous flowers. Honey Locust is especially susceptible to their attack.

During summer and late fall, the foliage attacked by these insects take on a pale color, with specks of greenish-white showing on the underside of the leaf. Their attack may cause locust to completely drop all its foliage during mid to late summer. This is the worst damage the leafhopper causes.

The insect overwinters in the egg stage and the nymphs appear when tree leaves reach full maturity. The nymphs as well as the adults suck the juices to cause damage.

A spray made up of two tablespoons of 50 per cent Sevin wettable powder per gallon of water is used to control the leafhopper. A mixture of two teaspoons of 57 per cent Malathion emulsion per gallon of water can also be used. For best results spray the foliage thoroughly.

For more information on controlling insect pests that attack Michigan trees and shrubs contact your local county cooperative extension office and ask for extension Bulletin 534, "Controlling Pests of Trees and Shrubs: A Guide for Home Gardeners." This bulletin can also be obtained by writing to: Michigan State University, Bulletin Office, Box 231, East Lansing, Michigan 48823. Single copies are available free to Michigan residents.
